Force Sensitive Resistor (FSR)
Sensor Data Sheet

TECHNICAL SPECIFICATIONS

> Range: 0.1 – 150 Kg
> Repeatability: ±2.5% (full scale)
> Consumption: ~0.4 mA
> Device rise time:
  1-2ms (Mechanical)
> Force accuracy:
  ±5% - ±25%
  (Depends on consistency of measurement & actuation system)
> Signal-to-noise ratio:
  Type 1: 19.3 ± 0.1 dB
  Type 2: 17.4 ± 0.1 dB
  Type 3: 31.7 ± 0.1 dB
  Type 4: 48.7 ± 0.1 dB
> Temperature range¹:
  [-30; 60] °C

SPECIAL FEATURES

> Life time: >10 million actuations
> Force resolution:
  ±0.5% (of full-scale force)
> Thin film technology:
  0.2-0.4 mm
  (Depending upon the type of sensor)
> Ready-to-use form factor
> Shielded miniaturized cables

AREA OF APPLICATIONS

> Biomechanics
> Robotic interaction control
> Biomechanical
> Kinematics
> Ergonomics
> Reaction time measurement
> Gait analysis
> Load distribution assessment
> Human-Computer Interaction
> Robotics & Cybernetics

¹ Depends on Type, for more detail, please, check Table-1
GENERAL DESCRIPTION

Force Sensing Resistors (FSR) sensors are devices that allow measuring static and dynamic forces applied to a contact surface. Their range of responses is basically depending on the variation of its electric resistance. From reaction time measurement to load distribution in shoe insoles, our thin film force Sensors offer good performance in most of the applications. The low-profile membrane (0.2-0.4 mm thickness) and miniaturized signal conditioning circuitry is ideal for minimally intrusive setups. Multiple sensing area dimensions and measurement ranges are available, enabling forces up to 150 Kg, although other options are also available upon request.

APPLICATION NOTES

FSR sensor comes with high accuracy, speed of response (rise time: 1-2ms), low thickness (0.2-0.4 mm thickness) and durability (>10 million actuations) makes it a suitable candidate for force sensing applications ranging from robotic interaction control and biomechanical fields. Plux Force sensors, based on FSR technology, were mainly designed for research in bio-mechanics and for applications involving the study of the pressure distribution in objects and infer critical pressure points on the human body while performing daily tasks (gait and rest), etc. To extract best response from the sensor, keep the actuator area, shape and compliance constant.

TRANSFER FUNCTION

The sensor requires frequent calibrations to provide reliable measurement, therefore a fixed transfer function does not exist and you need to calibrate the sensor in order to convert the acquired data into force. The calibration of the sensor can be done easily by using the following steps.

Step 1: Calculate voltage output of the sensor

[Type 1]

\[ V_{out} = \frac{ADC \times VCC}{2^n} \]

[Types 2, 3 and 4]

\[ V_{out} = \frac{ADC \times VCC}{2^n - 1} \]

\[ VCC: 3V \text{ (Operating Voltage)} \]
\[ V_{out}: \text{Voltage output of the sensor (V)} \]
\[ ADC: \text{Value sampled from the channel} \]
\[ n: \text{Number of bits of the channel} \]

Step 2: Calculate sensor conductance

\[ G = \frac{V_{out}}{(\text{Gain} \times VCC - V_{out}) \times R2} \]

\[ \text{Gain: 2} \]
\[ R2: 47 \text{ kΩ (Type-1) and 10 kΩ (Types 2, 3 and 4)} \]
\[ G: \text{Sensor conductance (mS)} \]

\[ \text{2 The number of bits for each channel depends on the resolution of the Analog-to-Digital Converter (ADC); in biosignalsplux the default is 16-bit resolution (} n = 16\text{), although 12-bit (} n = 12\text{) and 8-bit (} n = 8\text{) may also be found.} \]
Step 3: Acquire calibration signal

Compute the slope of the acquired signal using the sensor conductance computed in step 2.

Step 4: Convert data

The conductance is approximately proportional to the applied force. The force can be calculated by using the equation given below.

\[ F_{lb} = \frac{G}{S} \]

*\( F_{lb} \): Force weight equivalent in pounds (lb)
*\( S \): Slope of the calibration signal

**PHYSICAL CHARACTERISTICS**
